

# Multiple Follicles In Ovary

Ovarian disease the follicle in the ovary an ovarian cyst may form. Some women have more follicles than usual (polyendocrine Ovarian diseases are diseases or disorders of the ovary. Small ovarian cysts are common in healthy women. They can be classified as endocrine disorders or as disorders of the reproductive system

Ovarian follicle dominance development. In humans, there is usually only one dominant follicle per cycle. These selected follicles are known as the dominant follicles. Understanding Ovarian follicle dominance is the process where one or more follicles are selected per cycle to ovulate

Dewberry and blackberry, also an accessory fruit, with a fleshy receptacle Ranunculus In biology, folliculogenesis is the maturation of the ovarian follicle, a densely packed shell of somatic cells that contains an immature oocyte. Folliculogenesis describes the progression of a number of small primordial follicles into large preovulatory follicles that occurs in part during the menstrual cycle. Understanding this system allows medical practitioners to manipulate this process in women in order to help those who have reduced fertility through assisted reproductive technologies (ART). These treatments are able to help women with conditions such as polycystic ovary syndrome (PCOS) who have reduced fertility be able to conceive. These techniques can also be used in animal conservation and agriculture.

Ovarian follicle activation The process of development from a primordial follicle to a pre-ovulatory follicle is called folliculogenesis. The primordial Ovarian follicle activation can be defined as primordial follicles in the ovary moving from a quiescent (inactive) to a growing phase. The primordial follicle in the ovary is what makes up the "pool" of follicles that will be induced to enter growth and developmental changes that change them into pre-ovulatory follicles, ready to be released during ovulation. Ovarian follicle activation can be defined as primordial follicles in the ovary moving from a quiescent (inactive) to a growing phase

Magnolia Not all flowers with multiple ovaries form aggregate fruit; the ovaries of some flowers do not become tightly joined to make a larger fruit. As a result, many fruits form which are commonly mistaken to be of the aggregate variety. Aggregate fruits may also be accessory fruits, in which parts of the flower other than the ovary become fleshy and form part of the fruit. == References == Activation of Primordial Follicle Development ==

Aggregate fruit In contrast, a simple fruit develops from one ovary, and a multiple fruit develops from multiple flowers An aggregate fruit or etaerio () is a fruit that develops from the merger of several ovaries that were separated in a single flower. In contrast, a simple fruit develops from one ovary, and a multiple fruit develops from multiple flowers. In languages other than English, the meanings of "aggregate" and "multiple" fruit are reversed, so that "aggregate"

fruits merge several flowers. several ovaries that were separated in a single flower. The differences in meaning are due to a reversal in the terminology by John Lindley, which has been followed by most English-language authors

PMOS is diagnosed when a woman has at least two of the following three features: irregular menstrual periods, high testosterone or related symptoms (like excess facial hair), or an excess of antral ovarian follicles on ultrasound. Persons with PMOS are not more likely than those without to have true ovarian cysts. A blood test for high levels of anti-Müllerian hormone can replace the ultrasound in the diagnosis. Other symptoms associated with PMOS are heavy periods, acne, difficulty getting pregnant, and patches of darker skin.

In female mammals, each ovulatory cycle, or menstrual cycle in humans, a set number of ovarian follicles ovulate, each follicle releasing an egg that can be fertilised. If that female becomes pregnant, this is the maximum number of offspring she could have. The ovulated follicles come from a larger pool of growing follicles. Follicle dominance results from competition between follicles from this growing pool, as only some will be selected for further development. These selected follicles are known as the dominant follicles. In humans, there is usually only one dominant follicle per cycle.

**Drupelets:**

**Strawberry**, also an accessory fruit, with a fleshy receptacle

It is widely understood that androgens act primarily on preantral follicles and that this activity is important for preantral follicle growth. Additionally, it is thought that androgens are involved in primordial follicle activation. However, the influence of androgens on primordial follicle recruitment and whether this response is primary or secondary is still uncertain.

**Mild** symptoms include abdominal bloating and feeling of fullness, nausea, diarrhea, and slight weight gain. Moderate symptoms include weight gain greater than 1 kg (2.2 lb) per day, increased abdominal girth, vomiting, diarrhea, darker urine, decreased urine output, excessive thirst, and skin and/or hair feeling dry (in addition to mild symptoms). Severe symptoms are fullness/bloating above the waist, shortness of breath, pleural effusion, urination significantly darker or diminished in quantity, calf and chest pain, marked abdominal bloating or distention, and lower abdominal pain.

**Ovarian hyperstimulation syndrome** Most cases are mild, but rarely the condition is severe and can lead to serious illness or even death. factors include polycystic ovary syndrome, young age, low BMI, high antral follicle count, the development of many ovarian follicles under stimulation, extreme

**Ovarian hyperstimulation syndrome (OHSS)** is a medical condition that can occur in some women who take fertility medication to stimulate egg growth, and in other women in sporadic cases

**Structure**

**Raspberry**

**Underlying biology**

Other types of ovarian diseases listed in table include endometriosis, ovarian tumors, ovarian cancer, ovarian germ cell tumors, and ovarian low malignant potential tumors.

**Types**

The paired ovaries are located one on either side of the uterus, and connect with the uterus through the fallopian tubes. They are held in place by the ovarian ligament, and the suspensory ligament of the ovary.

Management focuses on relieving

symptoms... e3bb533bae Samaras: e3bb533bae

Ovulation induction of in vitro fertilization, and the aim is generally to develop multiple follicles (optimally between 11 and 14 antral follicles measuring 2–8 mm in diameter) Ovulation induction is the stimulation of ovulation by medication. It is usually used in the sense of stimulation of the development of ovarian follicles to reverse anovulation or oligoovulation e3bb533bae

Primordial follicles are activated to grow into antral follicles... e3bb533bae Contrary to male spermatogenesis, which can last indefinitely, folliculogenesis ends when the remaining follicles in the ovaries are incapable of responding to the hormonal cues that previously recruited some follicles to mature. This depletion in follicle supply signals the beginning of menopause. Each cycle of folliculogenesis, for a follicle, lasts around two and a half months. e3bb533bae

Ovary The ovarian follicles also produce and secrete inhibin to suppress the action of follicle stimulating hormone released by the anterior pituitary. A follicle contains a single oocyte surrounded The ovary (from Latin *ōvārium* 'egg') in the human female reproductive system is a gonad, a gland that produces sex hormones, and also controls the development and release of the egg cell (the female gamete). In the ovaries, the developing egg cells (or oocytes) mature in ovarian follicles. cells, the female gametes e3bb533bae

Liriodendron... e3bb533bae

Folliculogenesis remaining follicles in the ovaries are incapable of responding to the hormonal cues that previously recruited some follicles to mature. This depletion in follicle Although the process is similar in many animals, this article will deal exclusively with human folliculogenesis e3bb533bae

Many of the structural and functional features of the human ovary are shared with other mammals and vertebrates and ovaries of some kind are found in many invertebrates. e3bb533bae

Polyendocrine metabolic ovarian syndrome the name polycystic ovary syndrome: the &quot;cysts&quot; are not truly cysts, but arrested follicles. Having many follicles in the ovaries is also not unique to Polyendocrine metabolic ovarian syndrome (PMOS), previously called polycystic ovary syndrome (PCOS), is the most common hormonal disorder in women of reproductive age e3bb533bae

Gonadotropin-resistant ovary syndrome Spontaneous reversal of the receptor resistance may occur. Resistant ovaries result from a functional disturbance of the gonadotropin receptors in the ovarian follicles. elevated plasma follicle-stimulating hormone and luteinizing hormone - in the menopausal range - and that normal, multiple follicles are seen on ovarian Resistant ovary syndrome, previously known as Savage syndrome, is a cause of ovarian failure that can lead to secondary amenorrhea. It may be a cause of primary or secondary amenorrhea and is resistant to exogenous gonadotropin stimulation. Diagnosis of this condition requires that the patient has a normal 46,XX karyotype, normal secondary sexual characteristics, elevated plasma follicle-stimulating hormone and luteinizing hormone - in the menopausal range - and that normal,

multiple follicles are seen on ovarian biopsy

The exact cause of PMOS remains uncertain. There is a clear genetic component, but environmental factors are also thought to contribute. PMOS occurs in between 5% and 18% of women. The disorder is linked to insulin resistance, which is made worse by obesity. Insulin resistance and related excess insulin levels increase the risk of complications such as type 2 diabetes and liver disease. Those living with PMOS also have higher risk of endometrial cancer.

The ovary progresses through many stages beginning in the prenatal period through menopause.

== Scope ==

The individual parts of an aggregate fruit come in many forms. Common examples are:

== Signs and symptoms ==

Follicles:

Activation of the primordial follicle involves the following: a morphological change from flattened to cuboidal granulosa cells, proliferation of granulosa cells, formation of the protective zona pellucida layer, and growth of the oocyte.

If the egg fails to release from the follicle in the ovary an ovarian cyst may form. Small ovarian cysts are common in healthy women. Some women have more follicles than usual (polyendocrine metabolic ovarian syndrome), which inhibits the follicles to grow normally and this will cause cycle irregularities.

The term ovulation induction can potentially also be used for:

Achenes:

Each ovary measures around 3 cm in length by 1.5 cm wide and is 1 cm thick, and sits in a depression in the lateral wall of the pelvic cavity. This depression is called the ovarian fossa and measures around 4 cm x 3 cm x 2 cm. The fossa is bounded above by the external iliac artery and vein, in front by the obliterated umbilical artery, and behind by the...
