

Merge Sort Sorting Algorithm

== Application == e534fffc6

Bubble sort Bubble sort, sometimes referred to as sinking sort, is a simple sorting algorithm that repeatedly steps through the input list element by element, comparing Bubble sort, sometimes referred to as sinking sort, is a simple sorting algorithm that repeatedly steps through the input list element by element, comparing the current element with the one after it, swapping their values if needed. These passes through the list are repeated until no swaps have to be performed during a pass, meaning that the list has become fully sorted. The algorithm, which is a comparison sort, is named for the way the larger elements "bubble" up to the top of the list e534fffc6

Rather than merging A and B directly as with traditional methods, a block-based merge algorithm divides A into discrete blocks of size $\sqrt{A}$ (resulting in $\sqrt{A}$ number of blocks as well), inserts each A block into B such that the first value of each A block is less than or equal ($\leq$) to the B value immediately after it, then locally merges each A block with any B values between it and the next A block. e534fffc6 External sorting algorithms generally fall into two types, distribution sorting, which resembles quicksort, and external merge sort, which resembles merge sort. External merge sort typically uses a hybrid sort-merge strategy. In the sorting phase, chunks of data small enough to fit in main memory are read, sorted, and written out to a temporary file. In the merge phase, the sorted subfiles are combined into a single larger file. e534fffc6

Bucket sort It is a distribution sort, a generalization of pigeonhole sort that allows multiple keys per bucket,

and is a cousin of radix sort in the most-to-least significant digit flavor. Bucket sort can be implemented with comparisons and therefore can also be considered a comparison sort algorithm. The computational complexity depends on the algorithm used to sort each bucket, the number of buckets to use, and whether the input is uniformly distributed. Each bucket is then sorted individually, either using a different sorting algorithm, or by recursively applying the bucket sorting algorithm. Each bucket is then sorted individually. Bucket sort, or bin sort, is a sorting algorithm that works by distributing the elements of an array into a number of buckets. Bucket sort, or bin sort, is a sorting algorithm that works by distributing the elements of an array into a number of buckets

Sorting algorithm sorting is important for optimizing the efficiency of other algorithms (such as search and merge algorithms) that require input data to be in sorted lists. In computer science, a sorting algorithm is an algorithm that puts elements of a list into an order. Efficient sorting is important for optimizing the efficiency of other algorithms (such as search and merge algorithms) that require input data to be in sorted lists. Sorting is also often useful for canonicalizing data and for producing human-readable output. The most frequently used orders are numerical order and lexicographical order, and either ascending order or descending order

As merges still require a separate buffer large...

Merge sort Merge sort (also commonly spelled as mergesort or merge-sort) is an efficient, general-purpose, comparison-based sorting algorithm. Merge sort is a divide-and-conquer algorithm that was invented by John von Neumann in 1945. A detailed description and analysis of bottom-up merge sort appeared in a report by Goldstine and von Neumann as

early as 1948. Most implementations of merge sort are stable, which means that the relative order of equal elements is the same between the input and output. Most implementations Merge sort (also commonly spelled as mergesort or merge-sort) is an efficient, general-purpose, comparison-based sorting algorithm

== Algorithm ==

Block sort It gets its name from the observation that merging two sorted lists, A and B, is equivalent to breaking A into evenly sized blocks, inserting each A block into B under special rules, and merging AB pairs. **Block sort**, or **block merge sort**, is a sorting algorithm combining at least two merge operations with an insertion sort to arrive at $O(n \log n)$ (see **Big O notation**) in-place stable sorting time

Bucket sort works as follows: Scatter: Go over the original array, putting each object in its bucket. Merge-insertion sort performs the following steps, on an input The earliest description of the bubble sort algorithm was in a 1956 paper by mathematician and actuary Edward Harry Friend, *Sorting on electronic computer systems*, published in the third issue of the third volume of the *Journal of the Association for Computing Machinery (ACM)*, as a "Sorting exchange algorithm." Friend described the fundamentals of the algorithm, and although initially his paper went unnoticed, some years later it was rediscovered... It performs poorly in real-world use and is used primarily as an educational tool. More efficient algorithms such as quicksort, timsort, or merge sort are used by the sorting libraries built into popular programming languages such as Python and Java.

External sorting Thus, external sorting algorithms are

external memory algorithms and thus applicable in the external memory model of computation. External sorting is a class of sorting algorithms that can handle massive amounts of data. External sorting is required when the data being sorted do not fit into the main memory of a computing device (usually RAM) and instead they must reside in the slower external memory, usually a disk drive.

Although some algorithms are designed for sequential access, the highest-performing algorithms assume data is stored in a data structure which allows random access. One practical algorithm for $O(n \log n)$ in-place merging was proposed by Pok-Son Kim and Arne Kutzner in 2008. Conceptually, a merge sort works as follows: Formally, the output of any sorting algorithm must satisfy two conditions:

Overview

Merge-insertion sort R. and Selmer In computer science, merge-insertion sort or the Ford-Johnson algorithm is a comparison sorting algorithm published in 1959 by L. Ford Jr. It uses fewer comparisons in the worst case than the best previously known algorithms, binary insertion sort and merge sort, and for 20 years it was the sorting algorithm with the fewest known comparisons. Johnson. R. and Selmer M. Although not of practical significance, it remains of theoretical interest in connection with the problem of sorting with a minimum number of comparisons. The same algorithm may have also been independently discovered by Stanisław Trybuła and Czen Ping. Ford Jr. In computer science, merge-insertion sort or the Ford-Johnson algorithm is a comparison sorting algorithm published in 1959 by L.

Set up an array of initially empty "buckets".

Sort each non-empty bucket. e534ffffc6

Sort-merge join The basic The sort-merge join (also known as merge join) is a join algorithm and is used in the implementation of a relational database management system. The sort-merge join (also known as merge join) is a join algorithm and is used in the implementation of a relational database management system e534ffffc6

O e534ffffc6 The output is a permutation (a reordering, yet retaining all of the original elements) of the input. e534ffffc6 The output is in monotonic order (each element is no smaller/larger than the previous element, according to the required order). e534ffffc6

Merge algorithm These algorithms are used as subroutines in various sorting algorithms, most famously merge sort. These algorithms are used as subroutines in various sorting algorithms, most famously merge sort. The merge algorithm plays a critical Merge algorithms are a family of algorithms that take multiple sorted lists as input and produce a single list as output, containing all the elements of the inputs lists in sorted order. lists in sorted order e534ffffc6

Bitonic sorter It is also used as a construction method for building a sorting network. The algorithm was devised by Ken Batcher. It is also used as a construction method for building a sorting network. The resulting sorting networks consist of. The algorithm was devised by Ken Batcher Bitonic mergesort is a parallel algorithm for sorting. mergesort is a parallel algorithm for sorting e534ffffc6

The basic problem of a join algorithm is to find, for each distinct value of the join attribute, the set of tuples in each relation which display that value. The key idea of the sort-merge algorithm is to first sort the relations by the join attribute, so that interleaved linear scans will encounter these sets at the same time.

The essential principle is implemented, for example, by the traditional Unix join command. e534ffffc6 Gather: Visit the buckets in order and put all elements back into the original array. e534ffffc6 In practice, the most expensive part of performing a sort-merge join is arranging for both inputs to the algorithm to be presented in sorted order. This can be achieved via an explicit sort operation (often an external sort), or by taking advantage of a pre-existing ordering in one or both of the join relations. The latter condition, called interesting order, can occur because an input to the join might be produced by an index scan of a tree-based index, another merge join, or some other plan operator that happens to produce output sorted on an appropriate key. Interesting orders need not be serendipitous: the optimizer may seek... e534ffffc6 == Model == e534ffffc6 The outer loop of block sort is identical to a bottom-up merge sort, where each level of the sort merges pairs of subarrays, A and B, in sizes of 1, then 2, then 4, 8, 16, and so on, until both subarrays combined are the array itself. e534ffffc6 == History == e534ffffc6
