NIOSH Event tree analysis (ETA) is a forward, top-down, logical modeling technique for both success and failure that explores responses through a single initiating event and lays a path for assessing probabilities of the outcomes and overall system analysis 9774a2298c

Electrical connectors carry signals and power between parts of a system that may need to be separated during manufacturing, while in use, or when maintenance is required. Each connector that is part of a mating connector pair may be part of an electrical cable assembly (in which the unmated connector has some freedom of movement), or part of a chassis or other assembly (in which the connector position is fixed). In most pairs of mating connectors, one connector is fitted with an array of socket contacts and the other connector has a corresponding array of pin (or other shaped) contacts, as illustrated in Figure 1. These are sometimes called female and male contacts. Contacts are held in fixed positions within the connector body by a solid rectangular or cylindrical... 9774a2298c The process acts as a structured safety check during the design phase. Engineers systematically review every component to ask: "What if this part fails?" (Failure Mode), "What happens to the system?" (Failure Effect), and "Is this risk acceptable?" (Criticality). For example, in an aircraft design, a failure in a navigation light might be ranked as low criticality (minor inconvenience), while a failure in the landing gear would be ranked as high criticality (catastrophic). This prioritization helps engineering teams focus their limited resources on fixing the most dangerous problems first. 9774a2298c A few different types of FMEA analyses exist, such as: 9774a2298c The effect of each component failure mode on the product functionality, 9774a2298c

Accident analysis Its retrospective nature means that accident analysis is primarily an exercise of directed explanation; conducted using the theories or methods the analyst has to hand, which directs the way in which the events, aspects, or features of accident phenomena are highlighted and explained. These analyses are also invaluable in determining ways to prevent future incidents from occurring. Five Why's Model: Also known as "Why-Because" Accident analysis is a process carried out in order to determine the cause or causes of an accident (that can result in single or multiple outcomes) so as to prevent further accidents of a similar kind. It is part of accident investigation or incident investigation. Accident investigators, particularly those in the aircraft industry, are colloquially known as "tin-kickers". Health and safety and patient safety professionals prefer using the term "incident" in place of the term "accident". model, Ishikawa (fishbone) diagram, the Fault Tree Analysis (FTA), or the Failure Mode and Effect Analysis (FMEA). They provide good insight by determining root causes, into what failures occurred that led to the incident. These analyses may be performed by a range of experts, including forensic scientists, forensic engineers or health and safety advisers 9774a2298c

This technique may be applied to a system early in the design process to identify potential issues that may arise, rather than correcting the issues after they occur. With this forward logic process, use of ETA as a tool in risk assessment can help to prevent negative outcomes from occurring, by providing a risk assessor with the probability of occurrence. ETA uses a type of modeling technique called "event tree", which branches events from one single event using Boolean logic. 9774a2298c

A part failure mode is the way in which a component failed "functionally" on the component level. Often a part has only a few failure modes. For example, a relay may fail to open or close contacts on demand. The failure mechanism that caused this can be of many different kinds, and often multiple factors play a role at the same time. They include corrosion, welding of contacts due to an abnormal electric current, return spring fatigue failure, unintended command failure, dust accumulation and blockage of mechanism, etc. Seldom only one cause (hazard) can be identified that creates system failures. The real root causes can in theory in most cases be traced back to some kind of human error, e.g. design failure, operational errors, management failures, maintenance induced failures, specification failures, etc.

9774a2298c Design 9774a2298c Given a component database calibrated with field failure data that is reasonably accurate, the method can predict device level failure rate per failure mode, useful life, automatic diagnostic effectiveness, and latent fault test effectiveness for a given application. The predictions have been shown to be more accurate than field warranty return analysis or even typical field failure analysis given that these methods depend on reports that typically do not have sufficient detail information in failure records. 9774a2298c

All components of a design, 9774a2298c Software 9774a2298c It can describe electronic, mechanical, or biological systems, in fields such as systems and reliability engineering, medicine and biology, or insurance and finance. It is usually denoted by the Greek letter 9774a2298c In aerospace, the more general term "system failure condition" is used for the "undesired state" / top event of the fault tree. These conditions are classified by the severity of their effects. The most severe conditions require the most extensive fault tree analysis. These system failure conditions and their classification are often previously determined in the functional hazard analysis. 9774a2298c == How Connectors Work == 9774a2298c Human Factors 9774a2298c == Usage == 9774a2298c The ability of any automatic diagnostics to detect the failure, 9774a2298c == Forensic investigation == 9774a2298c According to Bloch and Geitner, "machinery failures reveal a reaction chain of cause and effect... usually a deficiency commonly referred to as the symptom...". Failure analysis can save money, lives, and resources if done correctly and acted upon. It is an important discipline in many branches of manufacturing industry, such as the electronics industry, where it is a vital tool used in the development of new products and for the improvement of existing products. The failure analysis process relies on collecting failed components for subsequent examination of the cause or causes of failure using a wide array of methods, especially microscopy and spectroscopy. Nondestructive testing (NDT) methods (such as industrial computed tomography scanning) are valuable because the failed products are unaffected by analysis, so inspection sometimes starts using these methods. 9774a2298c == Component failure/failure modes == 9774a2298c

Failure mode and effects analysis It was developed by reliability engineers in the late 1950s to study problems that might arise from malfunctions of military systems. An FMEA is often the first step of a system reliability study. For each component, the failure modes and their resulting effects on the rest of the system are recorded in a specific FMEA worksheet. Failure mode and effects analysis (FMEA; often written with "failure modes" in plural) is the process of reviewing as many components, assemblies, and Failure mode and effects analysis (FMEA; often written with "failure modes" in plural) is the process of reviewing as many components, assemblies, and subsystems as possible to identify potential failure modes in a system and their causes and effects. It was one of the first highly structured, systematic techniques for failure analysis. A FMEA can be a qualitative analysis, but may be put on a semi-quantitative basis with an RPN (Risk Priority Number) model. There are numerous variations of such worksheets. Related methods combine mathematical failure rate models with statistical failure mode ratio databases 9774a2298c

This analysis method is mainly used in safety engineering and reliability engineering to understand how systems can fail, to identify the best ways to reduce risk and to determine (or get a feeling for) event rates of a safety accident or a particular system level (functional) failure. Instead, NASA decided to rely on the use of failure modes and effects analysis (FMEA) and other Fault tree analysis (FTA) is a type of failure analysis in which an undesired state of a system is examined. FTA is used in the aerospace, nuclear power, chemical and process, pharmaceutical, petrochemical and other high-hazard industries; but is also used in fields as diverse as risk factor identification relating to social service system failure. FTA is also used in software engineering for debugging purposes and is closely related to cause-elimination technique used to detect bugs 9774a2298c
