Relativistic Doppler effect The relativistic Doppler effect is the change in frequency, wavelength and amplitude of light, caused by the relative motion of the source and the observer The relativistic Doppler effect is the change in frequency, wavelength and amplitude of light, caused by the relative motion of the source and the observer (as in the classical Doppler effect, first proposed by Christian Doppler in 1842), when taking into account effects described by the special theory of relativity 8b4aada147

They are the sensors for a number of systems including the senses of touch, hearing and balance, as well as participating in cardiovascular regulation and osmotic homeostasis (e 8b4aada147

All organisms, and apparently all cell types, sense and respond to mechanical stimuli. MSCs function as mechanotransducers capable of generating both electrical and ion flux signals as a response to external or internal stimuli. Under extreme turgor in bacteria, non selective MSCs such as MSCL and MSCS serve as safety valves to prevent lysis. In specialized cells of the higher organisms, other types of MSCs are probably the basis of... 8b4aada147 Jannik Bjerrum (son of Niels Bjerrum) developed the first general method for the determination of stability constants of metal-amine complexes in 1941. The reasons why this occurred at such a late date, nearly 50 years after Alfred Werner had proposed the correct structures for coordination complexes, have been

summarised by Beck and Nagypál. The key to Bjerrum's method was the use of the then recently developed glass electrode and pH meter to determine the concentration of hydrogen ions in solution. Bjerrum recognised... 8b4aada147

Coordination complex ligand and a charge balancing ion in a compound, for example the chloride ion in the cobaltammine chlorides and to explain many of the previously inexplicable A coordination complex is a chemical compound consisting of a central atom or ion, which is usually metallic and is called the coordination centre, and a surrounding array of bound molecules or ions, that are in turn known as ligands or complexing agents. Many metal-containing compounds, especially those that include transition metals (elements like titanium that belong to the periodic table's d-block), are coordination complexes 8b4aada147

== Summary of major results == 8b4aada147 Coordination complexes are so pervasive that their structures and reactions are described in many ways, sometimes confusingly. The atom within a ligand that is bonded to the central metal atom or ion is called the donor atom. In a typical complex, a metal ion is bonded to several donor

atoms, which can be the same or different. A polydentate (multiple bonded) ligand is a molecule or ion that bonds to the central atom through several of the ligand's atoms; ligands with 2, 3, 4 or even 6 bonds to the central atom are common. These complexes are called chelate complexes; the formation of such complexes is called chelation, complexation, and coordination. 8b4aada147

Valence (chemistry) Valence is generally understood to be the number of chemical bonds that each atom of a given chemical element typically forms. Double bonds are considered to be two bonds, triple bonds to be three, quadruple bonds to be four, quintuple bonds to be five and sextuple bonds to be six. Valence is not to be confused with the related concepts of the coordination number, the oxidation state, or the number of valence electrons for a given atom. In most compounds, the valence of hydrogen is 1, of oxygen is 2, of nitrogen is 3, and of carbon is 4. In the bifluoride ion ($[\text{HF}_2]^-$), for example, it forms a three-center four-electron bond with two fluoride atoms: In chemistry, the valence (US spelling) or valency (British spelling) of an atom is a measure of its combining capacity with other atoms when it forms chemical compounds or molecules. can form bonds with more than one atom 8b4aada147

The relativistic Doppler effect is different from the non-relativistic Doppler effect as the equations include the time dilation effect of special relativity and do not involve the medium of propagation as a reference point. They describe the total difference in observed frequencies and possess the required Lorentz symmetry. In the following table, it is assumed that for KIE is considered one of the most essential and sensitive tools for studying reaction mechanisms, the knowledge of which allows improvement... == Nomenclature and terminology == History == Often static electricity is a consequence of the triboelectric effect when the charge stays on one or both of the objects and is not conducted away.

The term triboelectricity has been used to refer to the field of study or the general phenomenon of the triboelectric effect, or to the static electricity that results from it. When there is no sliding, tribocharging is sometimes called contact electrification, and any static electricity generated is sometimes called contact electricity. The terms are often used interchangeably, and may be confused.

Ion Creangă's main contribution to fantasy and children's literature includes narratives structured around eponymous protagonists ("Harap Alb", "Ivan Turbincă", "Dănilă Prepeleac", "Stan Pătitul"), as well as fairy tales indebted to conventional forms

("The Story of the Pig", "The Goat and Her Three Kids", "The Mother with Three Daughters-in-Law", "The Old Man's Daughter and the Old Woman's Daughter"). Widely seen as masterpieces of the Romanian language and local humor, his writings occupy the middle ground between a collection of folkloric sources and an original contribution to a literary realism of rural inspiration. A main figure in 19th-century Romanian literature, he is best known for his Childhood Memories volume, his novellas and short stories, and his many anecdotes. Ion Creangă (Romanian pronunciation: [i'on 'kre̯aŋgə]; also known as Nică al lui Ștefan a Petrei, Ion Torcălău and Ioan Ștefănescu; March 1, 1837 – December 31, 1889) was a Moldavian, later Romanian writer, raconteur and schoolteacher. They are accompanied by a set of contributions to erotic literature, collectively known as his "corrosives"

In plants, magnesium is necessary for synthesis of chlorophyll and photosynthesis. Over 300 enzymes require the presence of magnesium ions for their catalytic action, including all enzymes utilizing or synthesizing ATP, or those that use other nucleotides to synthesize DNA and RNA.

The effect is named for Hermann Arthur Jahn and Edward Teller, who first reported studies about it in 1937

Triboelectric charge... The valence is the combining capacity of an atom of a given element, determined by the number of hydrogen atoms that it combines with.

Chlorine, as it has a valence of one, can be substituted for hydrogen in many compounds. Phosphorus has a valence 3 in phosphine (PH₃) and a valence...

This change in reaction rate is a quantum effect that occurs mainly because heavier isotopologues have lower vibrational frequencies and, therefore, lower ground-state vibrational energies, than their lighter counterparts. In most cases, this implies a greater energy input needed for heavier isotopologues to reach the transition state (or, in rare cases, dissociation limit), and therefore, a slower reaction rate. The

study of KIEs can help elucidate reaction mechanisms, and is occasionally exploited in drug development to improve unfavorable pharmacokinetics by targeted replacement of metabolically vulnerable C-H bonds with "stronger" C-D bonds (e.g., deutetrabenazine). 8b4aada147

Stability constants of complexes The hardness of a metal ion increases with oxidation state. It is a measure of the strength of the interaction between the reagents that come together to form the complex. The stability constant(s) provide(s) the information required to calculate the concentration(s) of the complex(es) in solution. though useful, is only semi-quantitative. There are two main kinds of complex: compounds formed by the interaction of a metal ion with a ligand and supramolecular complexes, such as host-guest complexes and complexes of anions. There are many areas of application in chemistry, biology and medicine. An example of this effect is given by the fact In coordination chemistry, a stability constant (also called formation constant or binding constant) is an equilibrium constant for the formation of a complex in solution 8b4aada147

Triboelectric effect It is ubiquitous, and occurs with differing amounts of charge transfer (tribocharge) for all solid materials. There is debate about whether electrons or ions are

The triboelectric effect (also known as triboelectricity, triboelectric charging, triboelectrification, or tribocharging) describes electric charge transfer between two objects when they contact or slide against each other. It can occur with different materials, such as the sole of a shoe on a carpet, or between two pieces of the same material. is included this can explain observations such as the effect of curvature or inhomogeneous charging. There is evidence that tribocharging can occur between combinations of solids, liquids and gases, for instance liquid flowing in a solid tube or an aircraft flying through air 8b4aada147

The Jahn-Teller effect, sometimes also referred to as Jahn-Teller distortion, describes the geometrical distortion of molecules and ions that results from certain electron configurations. The Jahn-Teller theorem essentially states that any non-linear molecule with a spatially degenerate electronic ground state will undergo a geometrical distortion that removes that degeneracy, because the distortion lowers the overall energy of the species. (For a description of another type of geometrical distortion that occurs in crystals with substitutional impurities, see article off-center ions.) 8b4aada147
