Management of cerebral palsy However, a recent meta-analysis comparing different exercise interventions reported that resistance training was associated. Often children with CP require orthoses, such as casts and splints, to correct or prevent Over time, the approach to cerebral palsy management has shifted away from narrow attempts to fix individual physical problems – such as spasticity in a particular limb – to making such treatments part of a larger goal of maximizing the person's independence and community engagement. Although such cross-over benefit might happen, not enough high-quality studies have been done to demonstrate it. However, the evidence base for the effectiveness of intervention programs reflecting the philosophy of independence has not yet caught up: effective interventions for body structures and functions have a strong evidence base, but evidence is lacking for effective interventions targeted toward participation, environment, or personal factors. AFOs have also been found to reduce energy expenditure. double support. Much of childhood therapy is aimed at improving gait and walking. Approximately 60% of people with CP are able to walk independently or with aids at adulthood. There is also no good evidence to show that an intervention that is effective at the body-specific level will result in an improvement at the activity level, or vice versa b8069aafc8
