

Radial Styloid Process Fracture

Radius (bone) It extends from the lateral side of the elbow to the thumb side of the wrist and runs parallel to the ulna. The radius is a long bone, prism-shaped and slightly curved longitudinally. : radii or radiuses) is one of the two large bones of the forearm, the other being the ulna. The ulna is longer than the radius, but the radius is thicker. projection, the styloid process, which gives attachment by its base to the tendon of the brachioradialis, and by its apex to the radial collateral ligament The radius or radial bone (pl

Treatment may include casting or surgery. Surgical reduction and casting is possible in the majority of cases in people over the age of 50. Pain management can be achieved during the reduction with procedural sedation and analgesia or a hematoma block. A year or two may be required for healing to occur. == Causes == Structure == Structure == Structure == Jonathan Hutchinson first described Chauffeur's fracture in 1866. The term "Chauffeur's fracture" originated from Just Lucas-Championnière in 1904. The name originates from early chauffeurs, who sustained these injuries when the car back-fired while the chauffeur was hand-cranking to start the car. The back-fire forced the crank backward into the chauffeur's palm and produced the characteristic styloid fracture. The corresponding bone in the leg is the tibia. Structure == Structure == The radius is part of three joints: the elbow and the wrist, both of which are synovial joints; and the radioulnar joint, which is a syndesmosis. At the elbow, it joins with the capitulum of the humerus, and in a separate region, with the ulna at the radial notch. At the wrist, the radius forms a joint with the ulna bone. The radioulnar joint allows for supination and pronation of the forearm. An anatomic description of the fracture is the easiest way to describe the fracture, determine treatment, and assess stability. It typically occurs as a result of a fall on an outstretched hand. Risk factors include osteoporosis. The diagnosis may be confirmed via X-rays. The tip of the ulna may also be broken. The ulna is a long bone found in the forearm that stretches from the elbow to the wrist, and when in standard anatomical position, is found on the medial side of the forearm. It is broader close to the elbow, and narrows as it approaches the wrist. Structure == Structure == Distal radius fractures are common, and are the most common type of fractures that are seen in children. Distal radius fractures represent between 25% and 50% of all broken bones and occur most commonly in young males and older females. A year or two may be required for healing to occur. Most children... Close to the elbow, the ulna has a bony process, the olecranon process, a hook-like structure that fits into the olecranon fossa of the humerus. This prevents hyperextension and forms a hinge joint with the trochlea of the humerus. There is

also a radial notch for the head of the radius, and the ulnar tuberosity to which muscles attach.

Chauffeur's fracture The injury is typically caused by compression of the scaphoid bone of the hand against the styloid process of the distal radius. It can be caused by falling onto an outstretched hand. Chauffeur's fracture, also known as Hutchinson fracture, is a type of intraarticular oblique fracture of the radial styloid process in the forearm. Treatment is often open reduction and internal fixation, which is surgical realignment of the bone fragments and fixation with pins, screws, or plates. The Chauffeur's fracture, also known as Hutchinson fracture, is a type of intraarticular oblique fracture of the radial styloid process in the forearm

Close to the wrist, the ulna has a styloid process. The fracture is most commonly caused by people falling onto a hard surface and breaking their fall with outstretched hand (FOOSH)-falling with wrists flexed would lead to a Smith...

Colles' fracture A higher amount A Colles' fracture is a type of fracture of the distal forearm in which the broken end of the radius is bent backwards. Symptoms may include pain, swelling, deformity, and bruising. Complications may include damage to the median nerve. dorsal tilt $>20^\circ$, comminuted fracture, avulsion of the ulnar styloid process, intraarticular displacement $>1\text{mm}$, loss of radial height $>2\text{mm}$

Classification of distal radius fractures Current systems rely on features such as involvement of adjacent joints (Frykman), anatomical displacement and method of injury (Melone), and severity (AO/OTA). At one extreme, a stable undisplaced extra-articular fracture can be managed conservatively with a cast immobilization. Individually, these classification systems have limited acceptance and there is currently no consensus. The two medial Classifications systems of distal radius fractures aim to aggregate patterns of injury which behave in predictable ways, to distinguish between conditions which have different outcomes or which need different treatments. breaks distal radius fractures down into 4 components: radial styloid, dorsal medial fragment, volar medial fragment, and radial shaft. On the other hand, a displaced intra-articular two-part shear fracture is often unstable and requires open reduction and internal fixation

== Structure == The triquetrum is one of the eight carpal bones of the hand. It is a three-faced bone found within the proximal row of carpal bones. Situated beneath the pisiform, it is one of the carpal bones that form the carpal arch, within which lies the carpal tunnel.

Distal radius fracture Distal radius fractures typically occur with the wrist bent back from 60 to 90 degrees. Symptoms include pain, bruising, and rapid-onset swelling. Radial styloid fracture would occur if the wrist is A distal radius fracture, also known as

wrist fracture, is a break of the part of the radius bone which is close to the wrist. The ulna bone may also be broken. of the bone

The radial styloid process is found on the lateral surface of the distal radius bone. It extends obliquely downward into a strong, conical projection. The tendon of the brachioradialis attaches at its base. The radial collateral ligament of the wrist attaches at its apex. The lateral surface is marked by a flat groove for the tendons of the abductor pollicis longus and extensor pollicis brevis.

Anatomical snuffbox The name originates from the use of this surface for placing and then sniffing powdered tobacco, or "snuff. anatomical snuffbox, the radial artery is closely related (<2 mm) with the superficial branch of radial nerve near the styloid process of radius in 48%, while The anatomical snuff box or snuffbox or foveola radialis is a triangular deepening on the radial, dorsal aspect of the hand—at the level of the carpal bones, specifically, the scaphoid and trapezium bones forming the floor. " It is sometimes referred to by its French name tabatière a388e5fb7c

Treatment is with casting for six weeks or surgery. Surgery is generally indicated if the joint surface is broken and does not line up, the radius is overly short, or the joint surface of the radius is tilted more than 10° backwards. Among those who are cast, repeated X-rays are recommended within three weeks to verify that a good position is maintained. a388e5fb7c The scaphoid is situated between the proximal and distal rows of carpal bones. It is located on the radial side of the wrist, adjacent to the styloid process of the radius. It articulates with the radius, lunate, trapezoid, trapezium, and capitate. Over 80% of the bone is covered in articular cartilage. a388e5fb7c

Radial styloid process The radial styloid process is found on the lateral The radial styloid process is a projection of bone on the lateral surface of the distal radius bone. The radial styloid process is a projection of bone on the lateral surface of the distal radius bone a388e5fb7c

In younger people, these fractures typically occur during sports or a motor vehicle collision. In older people, the most common cause is falling on an outstretched hand. Specific types include Colles, Smith, Barton, and Chauffeur's fractures. The diagnosis is generally suspected based on symptoms and confirmed with X-rays. a388e5fb7c

Ulna It is on the same side of the forearm as the little finger, running parallel to the radius, the forearm's other long bone. Close to the wrist, the ulna has a styloid process. also a radial notch for the head of the radius, and the ulnar tuberosity to which muscles attach. Longer and thinner than the radius, the ulna is considered to be the smaller long bone of the lower arm. Near

The ulna or ulnar bone (pl. The corresponding bone in the lower leg is the fibula. : ulnae or ulnas) is a long bone in the forearm stretching from the elbow to the wrist a388e5fb7c

Scaphoid bone It forms the radial border of the carpal tunnel. The scaphoid bone is the largest bone of the proximal row of wrist bones, its long axis being from above downward, lateralward, and forward. It articulates with the radius The scaphoid bone is one of the carpal bones of the wrist. It is located on the radial side of the wrist, adjacent to the styloid process of the radius. distal rows of carpal bones. It is approximately the size and shape of a medium cashew nut. It is situated between the hand and forearm on the thumb side of the wrist (also called the lateral or radial side) a388e5fb7c

== Anatomy == a388e5fb7c

Triquetral bone Instead, it is connected to and articulates with the ulna through the Triangular fibrocartilage disc and ligament, which forms part of the ulnocarpal joint capsule. It connects with the pisiform, hamate, and lunate bones. The triquetrum may be difficult The triquetral bone (; also called triquetrum, pyramidal, three-faced, and formerly cuneiform bone) is located in the wrist on the medial side of the proximal row of the carpus between the lunate and pisiform bones. It is the 2nd most commonly fractured carpal bone. palpation in an exam, the hand must be radially deviated so that the triquetrium moves out from under the ulnar styloid process. It is on the ulnar side of the hand, but does not directly articulate with the ulna a388e5fb7c

About 15% of people have a Colles' fracture at some point in their life. They occur more commonly in young adults and older people than in children and middle-aged adults. Women are more frequently affected than men. The fracture is named after Abraham Colles who described it in 1814. a388e5fb7c == History == a388e5fb7c
