Two-horse chariot races (bigae) were held in the Campus Martius, the area of Rome named for Mars, after which the right-hand horse of the winning team was transfixed by a spear, then sacrificed. The horse's head (caput) and tail (cauda) were cut off and used separately in the two subsequent parts of the ceremonies: two neighborhoods staged a fight for the right to display the head, and the freshly bloodied cauda was carried to the Regia for sprinkling the sacred hearth of Rome. eacaf3c47f

Horse trait: horses are able to sleep both standing up and lying down, with younger horses tending to sleep significantly more than adults. The horse has evolved over the past 45 to 55 million years from a small multi-toed creature, Eohippus, into the large single-toed animal of today, originally in North America. It belongs to the taxonomic family Equidae and is one of two extant subspecies of Equus ferus. Humans began domesticating horses around 4000 BCE in Central Asia, primarily associated with the Botai culture; and their domestication is believed to have been widespread by 3000 BCE. Female horses, called The horse (Equus ferus caballus) is a domesticated, one-toed, hoofed mammal. Horses in the subspecies caballus are domesticated, although some domesticated populations live in the wild as feral horses. These feral populations are not true wild horses, which are horses that have never been domesticated. There is an extensive, specialized vocabulary used to describe equine-related concepts, covering everything from anatomy to life stages, size, colors, markings, breeds, locomotion, and behavior eacaf3c47f

Stay apparatus The effect is that an animal can distribute its weight on three limbs while resting a fourth in a flexed, non-weight-bearing position. The relatively slim legs of certain large mammals, such as horses and cows, would be subject to dangerous levels of fatigue if not for the stay apparatus. Mongolia holds more than 5 million horses, an equine population which outnumbered the country's human population. The horses live outdoors all year at 30 °C (86 °F) in summer down to −40 °C (−40 °F) in winter, and search for food on their own. The mare's milk is processed into the national beverage *airag*, and some animals are slaughtered for meat. On the other hand, most light horse riding breeds were developed for speed, agility, alertness, and endurance; building on natural qualities that extended from their wild ancestors. eacaf3c47f

Sleep in animals These genes and the gene networks they regulate give rise to the internal circadian clock. The various criteria which biologists use to define sleep states have been observed in all other animal phyla, often with profound variation in function. The three categories of biological sleep schedules are diurnal, nocturnal, and crepuscular which characterize species whose waking periods mostly overlap with day, night, and twilight respectively. The large majority of such taxa with documented sleep physiology are bilaterians, though there is increasing evidence of sleep or sleep-like states in non-bilaterians such as Cassiopea jellyfish and hydra (both cnidarians), and sponges. Specific sleep patterns and durations vary widely among and sometimes within sleeping species, with some sleeping or foregoing sleep for extended periods. sleep. Others, such as some porpoises, engage in unihemispheric sleep where only one brain hemisphere sleeps at a time in order to. In all of these taxa except sponges, regulation of sleep is documented to involve genes whose transcription oscillates with time, known as circadian or clock genes. To show the necessity of sleep, one study argues that if sleep were not essential, one would expect to find Animal species that do not sleep at Sleep is broadly considered a biological
