In the early 21st century, however, childrenswear became heavily influenced by trends in adult fashion. Grandma bait is a retail industry term for expensive children's clothing. Due to the rise of social media platforms such as Instagram, celebrities and fashion bloggers have been using their accounts to post pictures of their children wearing luxury "street style" clothing, thus inspiring parents to dress their children as they would dress themselves. Good quality, well-designed garments are a priority for some parents, and children's clothing is getting a prime place in top-label stores and high-end fashion retail outlets. Clothes are also getting separately designed for boys and girls at a very early age. eaa6a90d59 Height is also important because it is closely correlated with other health components, such as life expectancy. Studies show that there is a correlation between small stature and a longer life expectancy. Individuals of small stature are also more likely to have lower blood pressure and are less likely to acquire cancer. The University of Hawaii has found that the "longevity gene" FOXO3 that reduces the effects of aging is more commonly found in individuals of small body size.

Classification of childhood weight This categorization
Classification of childhood weight is the categorization of a child's weight into several categories based on factors such as height, weight and age. This categorization helps doctors and parents identify developmental problems, such as under-nutrition or overweight, in their growing children and help them correct them in time. The World Health Organization and the Centers for Disease Control and Prevention (CDC) have both proposed their own standards. Growth charts can also be used to predict the expected adult height and weight of a child because, in general, children maintain a fairly constant growth curve. When a child deviates from his or her previously established growth curve, investigation into the cause is generally warranted. Parameters used to analyze growth charts include weight velocity (defined as rate of change in weight over time), height velocity (defined as rate of change in stature over time), and whether someone's growth chart crosses percentiles. For example, endocrine disorders can be...

Recently it has come to light that current growth charts for infants under 24 months overstate the expected weight of babies and lead to potentially obese children. This is because the original charts produced in 1977 were based on samples of middle-class white American babies on high-protein bottle-fed diets in Ohio. The World Health Organization has altered these targets in 2006 to represent a more healthy weight. == Development of tools

The BMI is a convenient rule of thumb used to broadly categorize a person based on tissue mass (muscle, fat, and bone) and height. Major adult BMI classifications are: underweight (under 18.5), normal weight (18.5 to 24.9), overweight (25 to 29.9), and obese (30 or more). When used to predict an individual's health, rather than as a statistical measurement for groups, the BMI has limitations that can make it less useful than some of the alternatives, especially when applied

to individuals with abdominal obesity, short stature, or high muscle mass. Defining the parameters for childhood obesity has created substantial public awareness over the past decades. Stuart/Meredith Growth Charts were among the earliest growth charts widely used in the United States but were limited by not being representative of the entire US pediatric population. Consequently, the need to develop growth charts that would encompass the ethnic, genetic, socioeconomic, environmental, and geographic diversity in the United States began in the 1970s. In 1977, new growth charts were developed by the National Center for Health Statistics (NCHS) based on data collected by the National Health Examination Surveys. However, these still contained many limitations and...
